

GMO and glyphosate wars rage

Three in one: EFSA set to re-licence glyphosate moves against IARC verdict that glyphosate

that FDA principle of GMO 'substantial equivalence' is bunk.

“ The results predict significant accumulation of formaldehyde and concomitant depletion of glutathione in the GMO, suggesting how a 'small' and single GM creates 'large' and systemic perturbations to molecular systems equilibria. ”

News on the GMO and glyphosate 'war' under way between conspiring with corporations is coming in so fast it's hard to follow. First, glyphosate. The EU's European Food Safety Authority (EFSA) has just announced it will re-licence glyphosate, the world's number one herbicide and the active ingredient in Roundup, also found in Dow's 'Enlist Duo' along with 2,4D.

Glyphosate was recently determined by the World Health Organization (IARC), to be a 'probable carcinogen'. It is time to [combat the global fallout](#) and make sure that it does not take away from a company a large share of its multi-billion dollar revenues.

Now it turns out, as [reported in the Guardian](#), that a key aspect of Risk Assessments, using information drawn from unpublished studies, "has drawn contrary conclusions from the IARC's data."

It therefore appears that the EFSA will re-approve the use of glyphosate, subjected to peer review. Documents, moreover, provided by the EFSA - no independent arbiter but an industry body dedicated to Monsanto UK - which even runs their website.

Based on this flimsy evidence, the German report found that glyphosate is "already grossly excessive 0.3mg to 0.5 mg per kilogram of bodyweight per day."

By contrast with industry dominated European regulators, IARC has a strict rule that it must base its judgements on the carcinogenicity of a substance.

More Monsanto tricks

Hot on the heels of this disgraceful news, [we hear from GMWatch](#) that Monsanto has asked WHO (formerly known as Cantox), to review WHO's verdict on glyphosate as a 'probable carcinogen'. Intertek [says](#) on its website, "We protect our customers' interests, helping them sell their products to market in a time-efficient and cost-effective manner."

In 2000 Intertek / Cantox's executive VP Ian C. Munro co-authored a reassuring paper for Monsanto employees, that [defended the safety of glyphosate herbicides](#). The paper claims that glyphosate causes no birth defects or other developmental toxicity. It concludes, unsurprisingly, that "the use of Roundup herbicide does not pose a health risk to humans".

The paper was published in the chemical industry-sponsored journal *Regulatory Toxicology and Environmental Chemistry*. The paper was investigated by a US Congressional Commission decision allowing the toxic chemical bisphenol A in infant formula and other foods.

"All this would matter less if Munro and his co-authors had cited credible sources in support of their developmental safety", says GMWatch. "But they cite unpublished studies from the industry. Strangely the authors fail to mention other studies from the same dossier showing malformations in lab animals."

"Monsanto claims in the article below that the process and findings of the new review are likely, since Monsanto will be paying or at least commissioning the review. This is reviewing industry studies, which thus far have been kept hidden from the public."

For more information on Cantox and its defence of glyphosate, see the Earth Open Access paper (pp.20-21).

'Substantial equivalence' of GMOs under attack

Finally a peer-reviewed paper published in the journal *Agricultural Sciences* has cast doubt on the (long substantiated and much criticised) principle employed by US regulators of 'substantial equivalence' (by assertion) much the same as non-GMO food and crops.

In their paper '[Do GMOs Accumulate Formaldehyde and Disrupt Molecular Systems? Answers](#)', authors V A Shiva Ayyadurai and Prabhakar Deonikar report on their 'systems biology' study that a small GM alteration in soybeans may be producing an excess of toxic formaldehyde.

"Proponents of GMOs assert that GMOs are safe since the FDA's policy of substantial equivalence compares them to their non-GMO counterparts, and argue that genetic modification (GM) is simply an extension of natural breeding, a form of 'genetic modification', though done over longer time scales", the authors write.

"Anti-GMO activists counter that GMOs are unsafe since substantial equivalence is based on the 1970s to assess safety of medical devices, which are not comparable to the complex systems that targeted GM is not plant breeding."

"Systems biology", they propose, "which aims to understand complexity of the whole system by studying its parts in a reductionist manner, may provide a framework to determine whether small or large, may affect emergent properties of the whole system."

They use a computational ('in silico') systems biology method to investigate known

Glycine max L. (soybean) under realistic conditions.

"The results predict significant accumulation of formaldehyde and concomitant dep. how a 'small' and single GM creates 'large' and systemic perturbations to molecular

"Regulatory agencies, currently reviewing rules for GMO safety, may wish to adopt combination of in silico, computational methods used herein, and subsequent target to develop a systems understanding of 'equivalence' using biomarkers, such as for metabolic disruptions, towards modernizing the safety assessment of GMOs."

Or in ordinary language, regulators should cease to just assume that GMOs are fine investigation and experimental verification on GMOs before declaring them 'safe'.
